\* Assistant Professor, Department of Computer science and engineering, PGP College of Arts and Science, Namakkal, India.

*Abstract*— This paper considers two types of protein data. First, data about protein function described in a number of ways, such as, GO terms and PFAM families. Second, data about whether individual proteins are experimentally associated with cancer by an anomalous elevation or lowering of their expressions within cancerous cells. We combine these two types of protein data and test whether the first type of data, that is, the functional descriptors, can predict the second type of data, that is, cancer-relatedness. By using data mining and machine learning, we derive a classifier algorithm that using only GO term and PFAM family descriptions of a protein can predict with over 73 percent accuracy whether it is associated with pancreatic cancer.

Index Terms— Data mining, GO term, pancreatic cancer, PFAM family, protein.

## I. INTRODUCTION

Data mining is increasingly applied to non-relational databases, including genome and protein databases [1]-[5]. Data mining and data classification methods are developed for protein structure and function [6]-[8], protein evolution [9], [10], protein interaction networks [11], and medical data that may include genomes or proteins [12]--[14]. In the present paper, preliminary versions of which were presented in [15] and [16], we focus on a pancreatic cancer protein database. This database was collected by Robert Powers and Bradley

Worley, in the Department of Chemistry at the University of Nebraska-Lincoln, based on earlier pancreatic cancer research [17]-[23].

Pancreatic cancer was chosen as a test case because it has the lowest survival rate among different types of cancer. Data mining was used to investigate the relationship among anomalous proteins, which have unusually high or low levels in pancreatic patients. Early recognition of some patterns developing among these anomalous proteins may allow treatment to start earlier and increase the survival rate of pancreatic cancer patients.

Data mining of protein databases poses special challenges

because many protein databases often contain set data types, whereas most data mining and machine learning algorithms assume relational database inputs. We overcame this problem by describing effecting ways to restructure the protein databases into relational databases. The restructured databases allowed the use of several types of classifiers, such as, Support Vector Machines (SVMs) and decision trees. Other types of data mining algorithms could be also used, but we chose these two types because they are currently the most frequently used data mining methods.

# II. BACKGROUND CONCEPTS AND TOOLS

In this section, part A gives an introduction to classifiers and part B describes the WEKA system that contains a library of implemented classifiers.

#### A. Classifiers

Let be a relation, where the set of attributes X= is called the feature space and the y attribute is called a label. Each tuple of the relation describes some entity based on specific values of the feature space and the label. For example, each row may describe a protein with specific feature attributes, such as, molecular weight, amino acid sequence etc., and a label attribute, such as, whether it is involved in pancreatic cancer.

Given such a relation R, a classifier is mapping from X to y. If a classifier is correct on all tuples of relation R, then the value of y can be always predicted from the values of X. In practice, the classifier may not be correct on all proteins. Further, classifiers are intended to be able to classify even those proteins that are new, not just those that are already in R.

Popular classifiers include decision trees and Support Vector Machines (SVMs). A decision tree is a tree which is read from the root towards the leaves, and whose internal nodes are tests and whose leaf nodes are categories [24]. For example, C4.5 is a well-known decision tree algorithm [25]. SVMs perform classification by constructing for relation R an n-dimensional hyper plane that optimally separates the data into two categories (for example when y = 0 and y = 1). An example of SVM is the libSVM implementation [26].

# B. The WEKA Library

In our experiments we used the Waikato Environment for Knowledge Analysis (WEKA) system developed at the University of Waikato [27], [28]. WEKA provides an extensive library of data mining and machine learning algorithms. In WEKA, the input data is a relation or table which is represented by an Attributes Relation File Format (ARFF) file. Each ARFF file starts with a title to let the user know what kind of data is stored in the file. The title is followed by a relation type and then all the attributes and their types. Finally, the attribute declarations are followed by the actual data rows.

# C. The Restructuring Method in Theory

In the pancreatic protein database collection of about eighty tables, we chose for our study the GO\_np and PFAM\_np tables, which contain data about pancreatic proteins that are not involved in cancer, and the GO\_pdac and PFAM\_pdac tables, which contain data about pancreatic proteins that are related to pancreatic cancer. GO\_np had 70,331, PFAM\_np had 7,054, GO\_pdac had 30,888, and PFAM\_pdac had 7,272 rows, that is, a total number of 115,545 rows.

A simplified version of the GO\_pdac looks as follows:

Table 1: GO_pdac table	
UID GO	
O43491	GO:0003779
O43491	GO:0005198
O43491	GO:0005886
O43491	GO:0008091
O43491	GO:0019898
O43491	GO:0030866
Q96C24	GO:0005215
Q96C24	GO:0005886
Q96C24	GO:0019898
Q96C24	GO:0030658
Q96C24	GO:0042043

The GO\_pdac table lists all (UID, GO) pairs, such that UID is the universal identifier of a pancreatic protein and GO is a feature descriptor, also called a GO term. The UID and the GO terms can be found in the UNIPROT database. There is a many-to-many relationship between the UIDs and the GO terms. For example, rows three and five with the same UID O43491 are related to two different GO terms, GO:0005886 and GO:0019898. On the other hand, rows three and eight with the same GO term GO:0005886 are related to two different UIDs, O43491 and Q96C24.

The GO\_np tables listed (UID, GO) pairs of non-pancreatic proteins. We merged the GO\_np and GO\_pdac tables without losing the information whether the protein is related to cancer or not. Hence we extended the GO\_np and the GO\_pdac tables with a Y column, which denotes whether the protein is related to pancreatic cancer or not. All the proteins in the GO\_np table are extended with a Y value of "0", while all the proteins in the GO\_pdac table are extended with a Y value of "1" by the following SQL query, which we call SQL 1 in Fig. 1:

Fig. 1 Generating GO\_PFAM\_merge.

```
Syntax for generating GO_PFAM_merge
create view GO_merge (UID, GO, Y) as
select UID, GO, 0 from GO_np
union
select UID, GO, 1 from GO_pdac;
After the above query is executed the GO_merge
table looks as follows:
```

 .....
 .....
 ....

We restructured or "flattened" the above table by an SQL query that transformed GO\_merge into another table GO\_merge\_flat in which all information about a single

protein appears in one row, as shown in Table 2.

In theory, the number of attributes in the restructured relation is n+2, where n is the number of distinct GO terms. Apart from UID and Y, these distinct GO terms form the attributes of the restructured relation. Below each GO term a '1' or '0' indicates whether the GO term applies to the protein indicated by the UID on the left.

# D. Simplifying the Restructuring Problem

The restructuring method described in the part C is not practical because it requires a huge matrix. For example, since GO\_merge table contains 17943 distinct UIDs and 7935 distinct GO terms, a straightforward application of the restructuring method would yield a table with entries. The WEKA and other machine learning systems simply cannot handle such big matrices. Moreover, the matrix could become even bigger when we consider not only GO terms but PFAM families and other attributes as described in part E below.

One possible way to reduce the size of the matrix is using Principal Component Analysis. Using Principal Component Analysis, the matrix could be rewritten into another matrix with a smaller number of columns. The new columns would be linear combinations of the existing columns, that is, the 7935 GO terms. While this would reduce the size of the

# International Journal of Emerging Technology in Computer Science & Electronics (IJETCSE) ISSN: 0976-1353 Volume 23 Issue 7 –OCTOBER 2016.

matrix and alleviate the runtime problems with WEKA and other machine learning systems, it would still not be a good solution.

Our ultimate goal is to be able to easily and accurately identify whether a new protein may be associated with cancer. Intuitively, we would like to characterize the cancer-related proteins based only on a small subset of the GO terms because it is impractical to test each of the 7935 GO terms whether it applies to a new protein.

The Principal Component Analysis would still require that we test each of the 7935 GO terms, and then linearly combine their (1 or 0) values to find the new columns. That is why the Principal Component Analysis would not yield a satisfying solution.

We need another method to find a small subset of the GO terms that characterizes the proteins in terms of cancer relatedness as accurately as the entire set of GO terms would characterize those. How can we find such a subset of the GO terms by using the restructuring matrix would be very sparse because most of the UIDs are characterized by less than ten GO terms. Hence most of the 7935 distinct GO terms would have a value of 0 in most rows. GO terms that occur only rarely do not connect many different UIDs hence they are not very useful as efficient cancer indicators. Hence we experimented with selecting only the top n most frequent GO terms. We observed that in general when n increases the accuracy also increases. At some point the increase in the accuracy diminishes with further increments in n. Hence it is not worth to increase further the value of n beyond that point. In our case, this value

{

```
create view GOcount(GO,count) as
select GO, count(*)
from GO_merge
group by GO;
}
```

The new table GOcount(GO,count) contains the count of each GO term. We extracted the top 200 most frequent GO terms into a text file as follows:

{
select GO from GOcount
order by count desc limit 200
into outfile `/tmp/MergeTop200GO.txt';
}

We wrote a C++ program, which is shown in detail in the code, to automatically generate the restructuring SQL query. Apart from some initialization and ending, the program repeatedly reads the next GO term from the input file MergeTop200GO.txt and writes to an output file SQL\_flatten.txt the line of the SQL query that corresponds to the GO term. Below is how the SQL\_flatten.txt file looks like.

select UID,

max(case when GO = GO:0016021 then 1 else 0 end) as GO:0016021,

max(case when GO = GO:0005515' then 1 else 0 end) as GO:0005515',

max(case when GO = GO:0005634' then 1 else 0 end) as

`GO:0005634',

max(case when GO = GO:0005737' then 1 else 0 end) as GO:0005737',

max(case when GO = GO:0008270' then 1 else 0 end) as GO:0008270',

max(case when GO = GO:0006350' then 1 else 0 end) as GO:0006350',

max(case when GO = GO:0007165' then 1 else 0 end) as GO:0007165',

max(case when GO = GO:0005886' then 1 else 0 end) as GO:0005886',

max(case when GO = GO:0005524' then 1 else 0 end) as GO:0005524',

max(case when GO = GO:0003677' then 1 else 0 end) as GO:0003677',

... Y from GO\_merg group by UID

When the above SQL query is executed, for each UID it checks all the GO terms. If any of the GO terms the UID is associated with matches a particular GO term for which we are creating a column in the flattened table, then that GO term will get a value of ``1" else it will get a value of ``0". The process then continues until it does not read any more UID groups.

E. Merging GO\_merge and PFAM\_merge

The PFAM table is similar to the GO table. The PFAM table contains the UID of proteins and the PFAM terms, which form another set of characterizations of proteins as an alternative to the GO term characterization. We can create PFAM\_merge by merging PFAM\_np and PFAM\_pdac similarly to how we created GO\_merge. Fig. 1 outlines the process of merging the GO\_merge and the PFAM\_merge tables together when we need to use both the GO and the PFAM terms. Table 3: is an example PFAM\_merge table. The SQL query, called SQL 2 in Fig. 1, to generate the PFAM\_merge table is similar to the SQL 1 query we saw before.

Table 3: The PFAM\_merge table.

group by UID
}
```

In our experiments, we used the top n most frequent GO terms as well as the top m most frequent PFAM terms, yielding a relation with n+m+2 attributes. We varied the values of n and m as described in the next section.

# III. EXPERIMENTAL RESULTS

Given a flattened file, as in Table 2, it is easy to generate an ARFF file, which is needed for the WEKA system. In the ARFF file, the UID attribute ranges over strings that describe protein IDs, and the "relation" attribute substitutes for the "Y" attribute. For example, Table 2 is described using ARFF as follows:

```
@relation GO_merge_flat
@attribute ``UID" {O43491, Q96C24}
@attribute ``GO:0003779" {0, 1}
@attribute ``GO:0005198" {0, 1}
@attribute ``GO:0005886" {0, 1}
@attribute ``GO:0008091" {0, 1}
@attribute ``GO:0019898" {0, 1}
@attribute ``GO:0030866" {0, 1}
@attribute ``relation" {0, 1}
@data
``O43491",1,1,0,1,1,1,1,1
``Q96C24",0,0,1,1,0,1,0,1
```

From our WEKA library, we used the libSVM support vector machine, which was previously added to the library, and the J48 decision tree. Both of these accepted input in ARFF format. The stratified cross-validation was used in all our classifications.

#### A. Support Vector Machine Results

Using libSVM with the GO\_merge\_flat file, WEKA gave the following:

CORRECTLY CLASSIFIED 12947 72.156 %

INCORRECTLY CLASSIFIED 4996 27.844 % TOTAL NUMBER 17943 100 %

WEKA also gave the following confusion matrix:

a b CLASSIFIED 12794 305 a=0 4691 153 b=1

The confusion matrix displays the relationship between two or more categorical variables. The number of correctly classified instances is the sum of the diagonals in the confusion matrix; all the others are incorrectly classified. For lib SVM with the PFAM\_merge file and stratified cross-validation, the data mining results with were as follows:

CORRECTLY CLASSIFIED 11590 71.707 % INCORRECTLY CLASSIFIED 4573 28.293 % TOTAL NUMBER 16163 100 %

The classification for all our instance was correct for about 71.7 % of the instances. Below is the confusion matrix:

a b CLASSIFIED 163 4263 a=0 310 11427 b=1

# B. Decision Tree Results

Our next set of experiments used the J48 decision tree. The decision tree with the GO\_merge\_flat file gave the following results:

CORRECTLY CLASSIFIED 12922 72.017 %

INCORRECTLY CLASSIFIED 5021 27.983 % TOTAL NUMBER 17943 100 %

The classification was again about 72 % correct. Below is the confusion matrix for the J48 decision tree:

a b CLASSIFIED 12562 537 a=0 4484 360 b=1

For decision tree with the PFAM\_merge\_flat file, the data mining results were as follows:

CORRECTLY CLASSIFIED 11719 72.505 %

INCORRECTLY CLASSIFIED 4444 27.495 %

TOTAL NUMBER 16163 100 %

The classification for all our instances was correct for over 72 % of the instances. It was slightly better than for GO\_merge\_flat with the decision tree classification. Below is the confusion matrix for the PFAM\_merge decision tree:

a b CLASSIFIED 144 4282 a=0 162 11575 b=1

# C. Improving the Accuracy

As we saw above, for both the GO\_merge\_flat and the PFAM\_merge\_flat files and both the lib SVM and the J48 the accuracy was around 72 %. A natural question is whether the accuracy can be improved by using both the GO terms and the PFAM families together. As we saw in Fig. 1, these terms can be combined in a relation GO\_PFAM\_merge. This file can be also flattened and represented in ARFF. We performed another set of experiments using WEKA and the GO\_PFAM\_merge\_flat file. The results for the lib SVM were the following:

# CORRECTLY CLASSIFIED 13099 73.003% INCORRECTLY CLASSIFIED 4844 26.997 %

TOTAL NUMBER 17943 100 %

Finally, the results for J48 were the following:

CORRECTLY CLASSIFIED 12936 72.095 % INCORRECTLY CLASSIFIED 5007 27.905 %

TOTAL NUMBER 17943 100 %

Our results from the GO\_PFAM\_merge analysis show that the lib SVM has the highest percentage of 73 % compared to 72 % for the decision tree.

# IV. PROSTAGLANDIN SYNTHESIS

Several recent studies have identified prostaglandin to be a major factor in pancreatic cancer [29]-[31]. We retrieved from the UNIPROT database (www.uniprot.org) all prostaglandin related proteins using the following query:

The query retrieved 89 proteins, but many of those were indicated to belong specifically to the liver, brain or other organs. By cross-checking with our pancreatic protein database, we identified the 24 pancreatic and prostaglandin related proteins shown in study [25]. The prostaglandin-related proteins interact with each other as shown in Fig. 2. we hypothesize that in pancreatic cancer the following chain of events takes place, where "anomaly" means either over expressed or under-expressed.

# Fig .2 Prostaglandin synthesis [32]

Due to various feedback loops, anomalies at some point in a chain may be compensated. In pancreatic cancer, we do not see further anomalies in the right-side chain of Fig. 2 starting with HPETE because Glutathione S-transferase (O60760) is not elevated. Similarly, we have little evidence for anomaly in the two other branches starting from Prostaglandin H2 because neither Prostacyclin synthase (Q16647) nor Thromboxane-A synthase (P24557) is anomalous. Hence the hypothetical process of pancreatic cancer can be summarized as follows: Q9NP80 P23219 P41222

Q15185 Q9P2B2

# V. DISCUSSION OF THE RESULTS

The results reveal that the characterizations of the pancreatic proteins by either GO terms or PFAM families can be used to predict with a good, that is, around 72 %, accuracy whether they are involved in cancer. Since the characterization of proteins is mainly based on their biological functions, the results imply that the likelihood of a protein being involved in cancer depends on its particular functions. Although the 72 % accuracy is interesting, for medical applications a higher, over 90 %, accuracy would be necessary. It is not clear how that higher accuracy could be achieved.

Our second set of experiments with both GO terms and PFAM families together gave a slight increase in accuracy to 73 % in the case of lib SVM. It is possible that by adding even more protein attributes, the accuracy of classification would improve further. It appears that proteins involved in certain general functions or particular protein networks within cells are more likely to be associated with cancer. It appears that within these particular protein synthesis networks entire pathways may be predisposed to anomalous behavior and cause cancer. In particular, we gave an in-depth study of the prostaglandin protein synthesis network. We are not aware of any previous work that called attention to the identified pathways starting from Q9NP80, although the anomalous behavior of Q9NP80 may be traced further back in an expanded network.

#### VI. CONCLUSION

Further study is needed to develop an early detection method for pancreatic cancer, enabling earlier treatment of cancer patients, and thereby increase their survival rate, which is currently one of the lowest among cancer patients. The result that the functional characterizations of proteins by either GO terms or PFAM families enable a good prediction of pancreatic cancer link may be also generalized to other types of cancers. The putative role of Q9NP80 in the early stages of pancreatic cancer should be further investigated.
